Class 8 Mini-Project: Unsupervised Learning Analysis of Human Breast Cancer Cells

Shivani Lakkaraju

Table of contents

Load Data	1
tidy to remove diagnosis	3
Principal component analysis (PCA)	5
Scaling	5
breast cancer PCA	8
Prediction with PCA	14

Load Data

Today we will practice applying our PCA and clustering methods from the last class on some breast cancer FNA data.

Let's get the data into R:

```
# Complete the following code to input the data and store as wisc.df
wisc.df <- read.csv("WisconsinCancer.csv", row.names=1)
head(wisc.df)</pre>
```

	diagnosis radi	us_mean t	exture_mean	perimeter_mean	area_mean

Q. how many samples/patients are in this dataset?

There are 569 samples in this dataset.

Q2. How many cancer/non-cancer diagnosis samples are in there?

```
sum(wisc.df$diagnosis == "M")
```

[1] 212

The table() function is a super useful utility for counting up the number of observations for each type.

```
table(wisc.df$diagnosis)
```

B M 357 212

In making a ML model we want to make sure there are equal sample sizes so the model is equally trained on both instead of overfit to 1.

Q3. How many columns/dimensions are there?

```
ncol(wisc.df)
```

[1] 31

Q4. how many columns are suffixed with "_mean"?

```
x <- grep("_mean", colnames(wisc.df))
length(x)</pre>
```

[1] 10

tidy to remove diagnosis

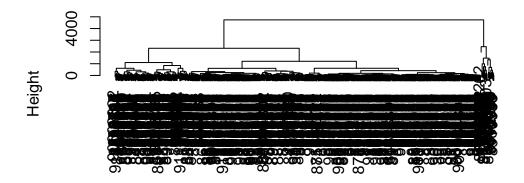

```
# Create diagnosis vector for later
diagnosis <- wisc.df$diagnosis

# We can use -1 here to remove the first column
wisc.data <- wisc.df[,-1]</pre>
```

#cluster the dataset with hclust() which wants a distance matrix as input.

```
hc.raw <- hclust(dist(wisc.data))
plot(hc.raw)</pre>
```

Cluster Dendrogram

dist(wisc.data) hclust (*, "complete")

To get some clusters out of this I can "cut" the tree at a given height:

```
grps <- cutree(hc.raw, h=4000)
table(grps)</pre>
```

grps 1 2 549 20

To see the correspondence of our cluster grps with the expert diagnosis, I can use table():

table(grps, diagnosis)

```
diagnosis
grps B M
1 357 192
2 0 20
```

That is not useful....

Principal component analysis (PCA)

Scaling

Scaling data before analysis is often critical.

Side note: The default for prcomp() is scale=FALSE

There is a dataset in R called mtcars which has loads of numbers about old cars.

head(mtcars)

```
mpg cyl disp hp drat

                                                 1.6152000
```

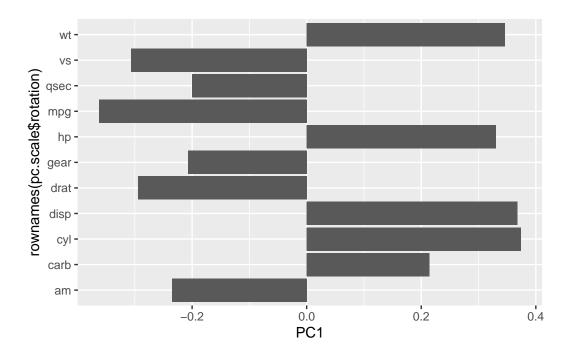

```
pc.noscale <- prcomp(mtcars, scale=FALSE)
pc.scale <- prcomp(mtcars, scale=TRUE)</pre>
```

Let's look at the loadings first:

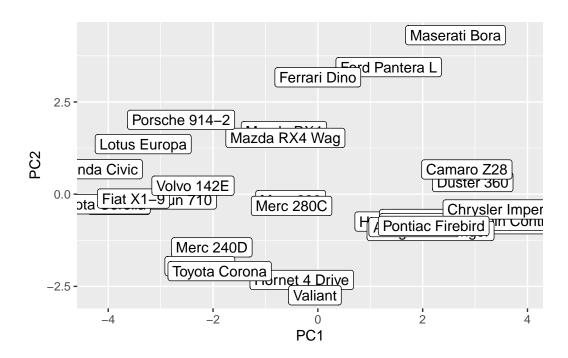

```
library(ggplot2)
ggplot(pc.noscale$rotation, aes(PC1, rownames(pc.noscale$rotation))) + geom_col()
```

ggplot(pc.scale\$rotation, aes(PC1, rownames(pc.scale\$rotation))) + geom_col()

The main PC result figure is often called a "score plot" or "PC plot" or PC1 VS PC2 plot".

```
y <- scale(mtcars)
round(colMeans(y))</pre>
```

```
mpg cyl disp hp drat wt qsec vs am gear carb 0 0 0 0 0 0 0 0 0 0 0
```

```
round(apply(y, 2, sd))
```

```
mpg cyl disp hp drat wt qsec vs am gear carb
1 1 1 1 1 1 1 1 1 1 1
```

key point: generally we want to "scale" our data before analysis to avoid being mislead due to your data having different measurement units.

breast cancer PCA

We will scale our data:

```
pca <- prcomp(wisc.data, scale=T)</pre>
```

See how well we are doing:

```
summary(pca)
```

Importance of components:

[1] "prcomp"

##combine PCA and clustering We saw earlier that clustering raw data alone was not useful.

We can use our new PC variables (our PCs) as a basis for clustering. Use our x PC scores and cluster in the PC1 and PC2 subspace.

```
hc.pca <- hclust(dist(pca$x[,1:2]), method="ward.D2")
plot(hc.pca)
abline(h=70, col="blue")</pre>
```

Cluster Dendrogram

dist(pca\$x[, 1:2]) hclust (*, "ward.D2")

Q. does your clustering help separate cancer from non-cancer samples (ie: diagnosis M v B)?

```
grps2 <- cutree(hc.pca, h=70)
table(grps2)</pre>
```

grps2 1 2 195 374

table(grps2, diagnosis)

diagnosis grps2 B M 1 18 177 2 339 35

Positive cancer samples "M" Negative non-cancer samples "B"

True: cluster 1 False: cluster 2

How many TP (true positive) do we have?

How many FP (false positive) do we have?

Sensitivity: TP/(TP+FN) Specificity: TN/(TN+FN)

Prediction with PCA

we can take new data from UofM and project it onto our new variables (PCs).

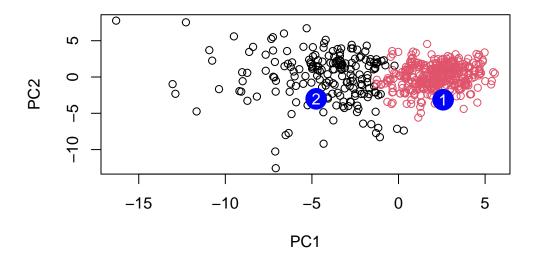

```
#url <- "new_samples.csv"
#read data
url <- "https://tinyurl.com/new-samples-CSV"
new <- read.csv(url)
#projection
npc <- predict(pca, newdata=new)
npc</pre>
